

Calendar test (route A): all paper figures under the angular calendar

Conversion: mean-preserving 12x12 matrix per orbit (angcal.py), months = fixed arcs of solar longitude anchored at the vernal equinox (day 80). Validated against exact angular insolation (max error 2.8 W m^{-2}). Fig. 2 (method snapshot) is calendar-independent and not repeated. Table 1 numbers not regenerated. Each following page: TOP = fixed-day calendar (paper version), BOTTOM = angular calendar.

the lever itself, fixed vs angular (bars ride $0.228 \times$ insolation exactly)

precession lever, fixed vs angular calendar ($e=0.058$)
